Q1. If the decay rate of  $\Delta^{++} = \Gamma^{++}$  what is the decay rate of  $\Delta^+$ ?

Solution: In the decay isospin is conserved. Since  $I = 3/2$  for the  $\Delta$  the final state can only be  $I = 3/2$ . The decay Of  $\Delta^+$  can occur through the channels

$$\Delta^+ \rightarrow p + \pi^0$$

and

$$\Delta^+ \rightarrow n + \pi^+$$

We have and

$$|n\pi^+ \rangle = \left(\frac{1}{3}\right)^{1/2} |I = 3/2, I_z = 1/2 \rangle + \left(\frac{2}{3}\right)^{1/2} |I = 1/2, I_z = 1/2 \rangle$$

$$|p\pi^0 \rangle = \left(\frac{2}{3}\right)^{1/2} |I = 3/2, I_z = 1/2 \rangle + \left(\frac{1}{3}\right)^{1/2} |I = 1/2, I_z = 1/2 \rangle$$

Thus

$$\langle n\pi^+ | M | \Delta^+ \rangle = \left(\frac{1}{3}\right)^{1/2} \langle I = 3/2, I_z = 1/2 | M | \Delta^+ \rangle$$

$$\langle p\pi^0 | M | \Delta^+ \rangle = \left(\frac{2}{3}\right)^{1/2} \langle I = 3/2, I_z = 1/2 | M | \Delta^+ \rangle$$

Hence

$$\Gamma^+(n\pi^+) = \frac{1}{3}\Gamma^{++}$$

$$\Gamma^+(p\pi^0) = \frac{2}{3}\Gamma^{++}$$

Total rate is

$$\Gamma^+ = \Gamma^+(n\pi^+) + \Gamma^+(p\pi^0) = \Gamma^{++}$$

2. A particle X of mass  $M_X$  decays to two particles Y (mass  $M_Y$ ). The decay distribution is isotropic in the rest frame of X. Consider a frame in which X is travelling with energy  $E_X$  along the 3rd direction. Show that the

energy distribution in the moving frame is constant- that is if  $dN_Y$  is the number emitted in the energy range  $E_Y$  to  $E_Y + dE_Y$  show that

$$\frac{dN_Y}{dE_Y} = \text{constant}$$

and

$$\frac{\gamma}{2}[M_X - \beta\sqrt{(M_X^2 - 4M_Y^2)}] < E_Y < \frac{\gamma}{2}[M_X + \beta\sqrt{(M_X^2 - 4M_Y^2)}]$$

where  $\gamma = E_X/M_X$  and  $\beta = \sqrt{(E_X^2 - M_X^2)}/E_X$

Solution:

Let the momentum four vector of  $Y$  in the rest frame of  $X$  be  $(E_Y(r), P_Y(r)\sin(\theta), 0, P_Y(r)\cos(\theta))$ .  $\theta$  is the angle made by the momentum vector of  $Y$  in the rest frame of  $X$ . Here  $E_Y(r) = m_X/2$ ;  $p_Y(r) = (m_X^2/4 - m_Y^2)^{1/2}$ . We can get the energy in the frame in which  $X$  is moving by a Lorentz transformation

$$E_Y = \gamma(E_Y(r) + \beta P_Y(r)\cos(\theta))$$

where  $\gamma = E_X/m_X$ ;  $\beta = (E_X^2 - m_X^2)^{1/2}/E_X$ . This implies (using  $E_Y(r) = m_X/2$ ;  $p_Y(r) = (m_X^2/4 - m_Y^2)^{1/2}$ )

$$\frac{\gamma}{2}[M_X - \beta\sqrt{(M_X^2 - 4M_Y^2)}] < E_Y < \frac{\gamma}{2}[M_X + \beta\sqrt{(M_X^2 - 4M_Y^2)}]$$

Thus  $\frac{dE_Y}{d\cos(\theta)} = \gamma\beta P_Y$  and

$$\frac{dN}{dE_Y} = \frac{dN_Y}{d\cos(\theta)} \frac{d\cos(\theta)}{dE_Y} = \frac{1}{\gamma\beta} \times \text{constant}$$

as  $\frac{dN_Y}{d\cos(\theta)}$  is a constant for isotropic distribution.

Q3. A  $\rho^0$  meson is in the rest frame in the eigenstate of spin operator  $S_3$  with eigenvalue 0. Write the matrix element for the decay of  $\rho^0$  to  $\pi^+\pi^-$ . Find the angular distribution of the decay products. ( You can use the matrix element

$$M = g\epsilon^\mu(p_{\pi^+} - p_{\pi^-})_\mu$$

where  $g$  is a constant.)  $\epsilon^\mu$  represents the polarization vector of  $\rho^0$  meson and  $p_{\pi^+}, p_{\pi^-}$  are the four momenta of the  $\pi^+, \pi^-$  respectively.

Solution:

In the notation for the spin operators  $(S_i)_{jk} = -i\epsilon_{ijk}$  we have the eigenvector for  $S_3$  with eigenvalue zero is

$$\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$$

Thus  $\epsilon^0 = \epsilon^1 = \epsilon^2 = 0; \epsilon^3 = 1$ . the matrix element for  $\rho$ - decay becomes

$$M = g(p_{\pi^+} - p_{\pi^-})_3 = -2gp_{\pi^+}^3 = -2g|p_{\pi^+}|\cos(\theta)$$

where  $\cos(\theta)$  is the angle with respect to the spin for the  $\rho$ . We are in the rest frame of  $\rho$  and so  $p_{\pi^+3} = -p_{\pi^-3}$ . The angular distribution  $\propto |M|^2 \propto \cos^2(\theta)$
